## Introduction

In this document is shown the docking methodology followed by the team Synthetic Biobots during the iGEM Design League 2022 season. Molecular docking is a process to couple proteins with their ligands; for this project molecular docking was performed in order to support the decision of using the proteins that were selected as part of the biosynthetic pathway of piperamide. The different steps necessary for its production are shown in the figure shown in the next page; in this figure all the steps required are marked with a number, this number is an identifier for the enzyme required to perform that step.

From all the enzymes used in the pathway, only 8 require a docking step for different reasons, these reasons can be that it is an enzyme that has not been isolated and even though a previous annotation step indicates it performs that reaction, molecular docking can provide better support for their selection and activity. Another reason to perform molecular docking is when the protein is known and has been isolated but we are using a molecule that is not the original ligand of the protein, in this case molecular docking can help to elucidate if the protein is capable of performing the reaction with a molecule with similar structure to its original ligand. The enzymes that are subject of molecular docking and the genes that code for these enzymes and will be studied are: 1 (Pn8.2617), 2 (Pn2.84), 4 (Pn1.1317), 5 (Pn3.4770, Pn7.1626), 6 (Pn16.1237, Pn16.1198), 8 (Pn4.3222), 9 (Pn2.2377) and 10 (2cwh).

For each of these genes it was performed a differential exon usage analysis between four different *Piper nigrum* tissues: fruit at 20 days stage, fruit at 40 days stage, leaf and panicle. This analysis can help us to visualize the expression level for each exon of the genes, this information allows us to select the exons of the gene to include in the modeling and in the following steps. This analysis was performed by using the Bioconductor library “DEXSeq”, to access the code used for this methodology please visit the GitHub repository of the team for iGEM Design League 2022 season, the Exon\_usage directory.<sup>10;3;24</sup> The STAR ultrafast universal RNA-seq aligner on the Galaxy project platform mapped the RNA-seq reads to the reference genome of *Piper nigrum* prior to the differential exon usage analysis.<sup>12;7;6</sup> Only results of relevance for the modeling and docking methods are shown in this document.

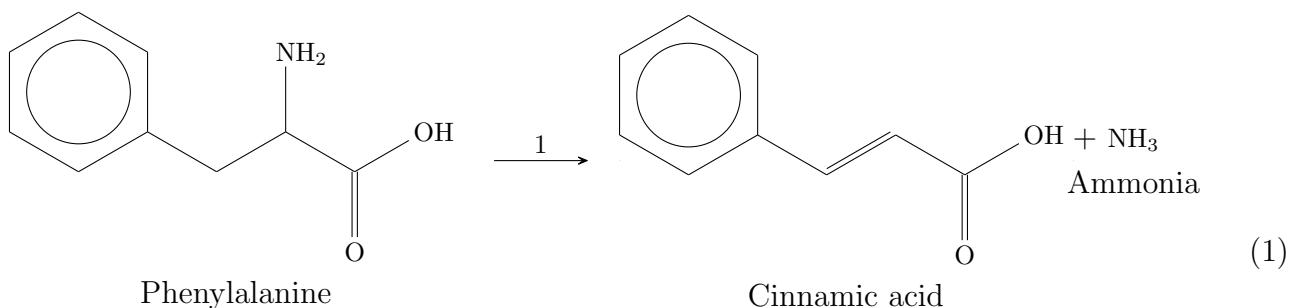

Biosynthetic pathway of piperamide.

# 1 Docking

## 1.1 Pn8.2617

The first reaction in the biosynthetic pathway of piperamide is performed by the enzyme phenylalanine ammonia-lyase, which is part of the phenylpropanoid biosynthesis pathway and catalyzes the reaction shown in Eq. 1. The gene Pn8.2617 was selected as the best candidate for enzyme 1, this selection was based on the fact that it obtained the highest score (1170.9) over the threshold (524.93) for KEGG Orthology ID K10775, with E-value  $\approx 0$ . This annotation was made with KofamKOALA.<sup>4</sup> With the exon usage analysis no relevant results were found.

The gene contains two exons that were considered when modeling the three-dimensional structure of the protein. The structure modeling was made by using an homology based methodology “SWISS-MODEL”.<sup>33,5</sup> This methodology is template based, in this case the template selected was a phenylalanine ammonia-lyase from *Petroselinum crispum* with PDB ID: 1w27; this protein has a 79.97% sequence identity to our query protein Pn8.2617 which makes it an appropriate template. The template was found with HHblits, a protein sequence searching algorithm that uses hmm-hmm alignment.<sup>23</sup> The model (Fig. 1) is found in a homo-tetrameric state, as the template is; it has a GMQE value of 0.84 and a QMEANDisCo Global value of  $0.81 \pm 0.05$  (Fig. 2). The QMEANDisCo value is a composite score value for single model quality estimation, this value is a function of underlying single model scores employing statistical potentials of mean force and a distance constraint based on the known structure of homologous proteins. QMEANDisCo value is

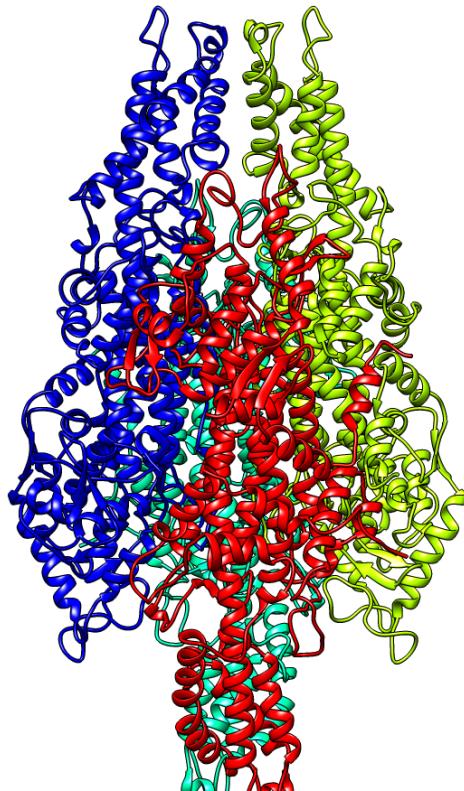

Figure 1: Pn8.2617 three-dimensional model.

calculated for every residue of the protein and the QMEANDisCo Global value is the average of these per residue scores, which aims to be a good approximation of the global overall quality of the model.<sup>26</sup> The ligand 3D conformer structure was obtained from PubChem with CID: 6140.

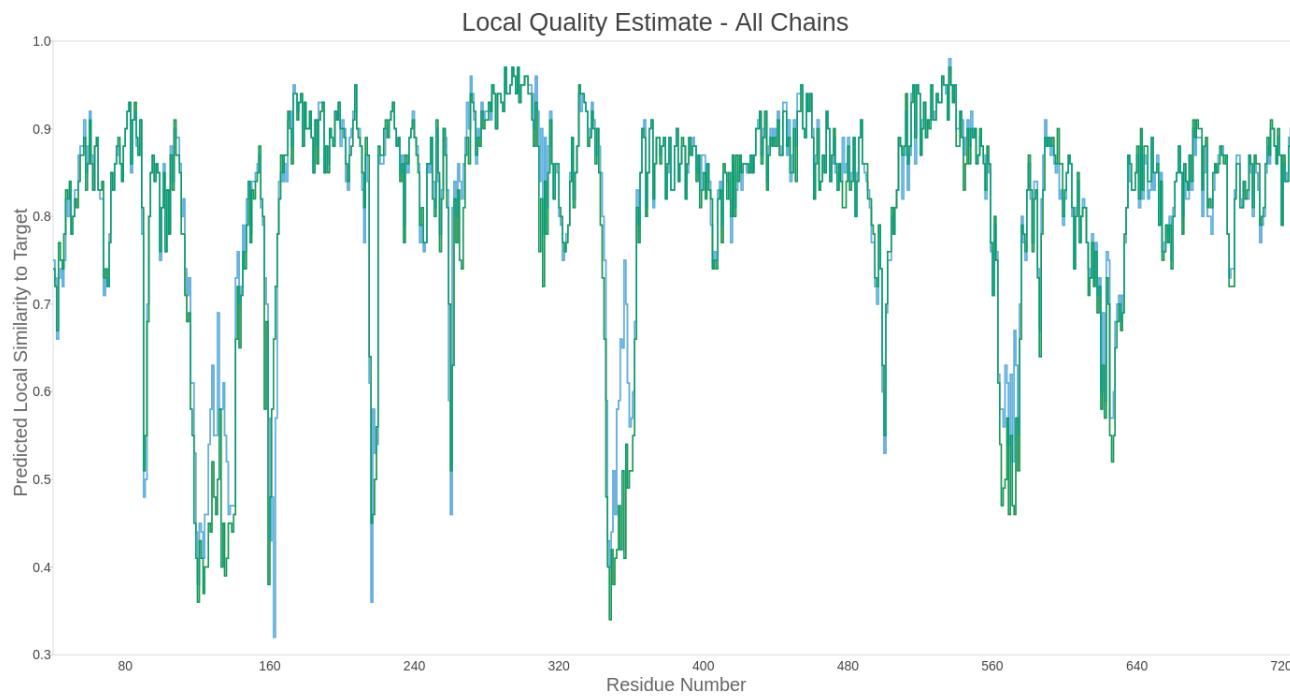

Figure 2: Pn8.2617 model QMEANDisCo.

Before docking was performed the protein and the ligand were energy minimized. The protein structure was minimized using UCSF ChimeraX software<sup>21;11</sup> and the steepest descent algorithm for 1000 steps with a step size of 0.02 Å; the force field AMBER ff14SB was used for standard residues, for non standard residues the semi-empirical AM1-BCC model that uses an additive bond charge corrections was selected since it has shown higher success rate than other force fields in docking methods.<sup>13;14;31</sup> In the same way the ligand was energy minimized by using the python library “rdkit” and the MMFF94 force field implemented within it.<sup>15;29</sup>

The preparation of the molecules for docking was made on AutoDockTools and Autodock Vina version 1.2.3 docked the protein and the ligand.<sup>20;8;30</sup> The grid box for the docking was selected based on the conserved domains found with the NCBI conserved domain search interface; we found the tetramer interface and active site conserved domains for phenylalanine ammonia-lyase from the CDD database.<sup>16;17</sup>. CASTp3 found the protein’s pockets, which are cavities on its surface into which solvent can enter; CASTp3 uses computational geometry to find these pockets mainly using Delaunay triangulation, alpha shape, and discrete flow.<sup>28</sup> As a result of molecular docking with Vina, nine different conformations of the ligand in the protein were found, these results are shown in Table 1.

The docked positions of the phenylalanine in the Pn8.2617 structure interacted with different aminoacid residues of the protein (Fig. 3). Some of these aminoacids were found in the conserved domain for the active site of the enzyme, like Phe 129, Leu 147, Leu 270, Asn 274, Tyr 365, Arg 368 and Asn 398; the rest of the aminoacids were not marked as conserved in the active site domain but were present in the pockets found by CASTp3: Phe 150, Leu 221, Phe 414, Lys 470, Glu 498, Asn 501 and Gln 502.

Table 1: Docking results of phenylalanine in Pn8.2617

Mode	Affinity (kcal/mol)	Dist. from best mode RMSD l.b	RMSD u.b
1	-6.278	0.0	0.0
2	-6.126	2.278	2.795
3	-6.098	1.934	2.262
4	-6.095	1.773	1.908
5	-6.013	1.735	2.332
6	-5.850	2.656	3.643
7	-5.847	1.749	2.333
8	-5.700	2.823	3.134
9	-5.670	3.526	4.412

A further analysis was carried out to elucidate the protein-ligand interactions of the best conformation obtained, which has a binding energy of -6.278 kcal/mol. A search for hydrogen bonds was performed using UCSF ChimeraX allowing relax constraints of 0.4 Å and 20 degrees, the bonds are shown as pseudobonds since they represent significant interactions between atoms other than covalent bonds, also because of the relax constraint these predictions can represent bonds within the tolerance values but not meeting the precise criteria.<sup>21;11;19</sup> Four pseudobonds were found between the ligand and two aminoacids of the protein, one pseudobond with Asn 501 and a distance of 2.022 Å and three with Arg 368 with distances of 2.240 Å, 2.322 Å and 2.438 Å. In Fig. 4 this pseudobonds and the ligand in its pocket are shown, the surface of the protein is colored based on its hydrophobicity using Kyte-Doolittle scale from lower (blue) to higher hydrophobicity (red).

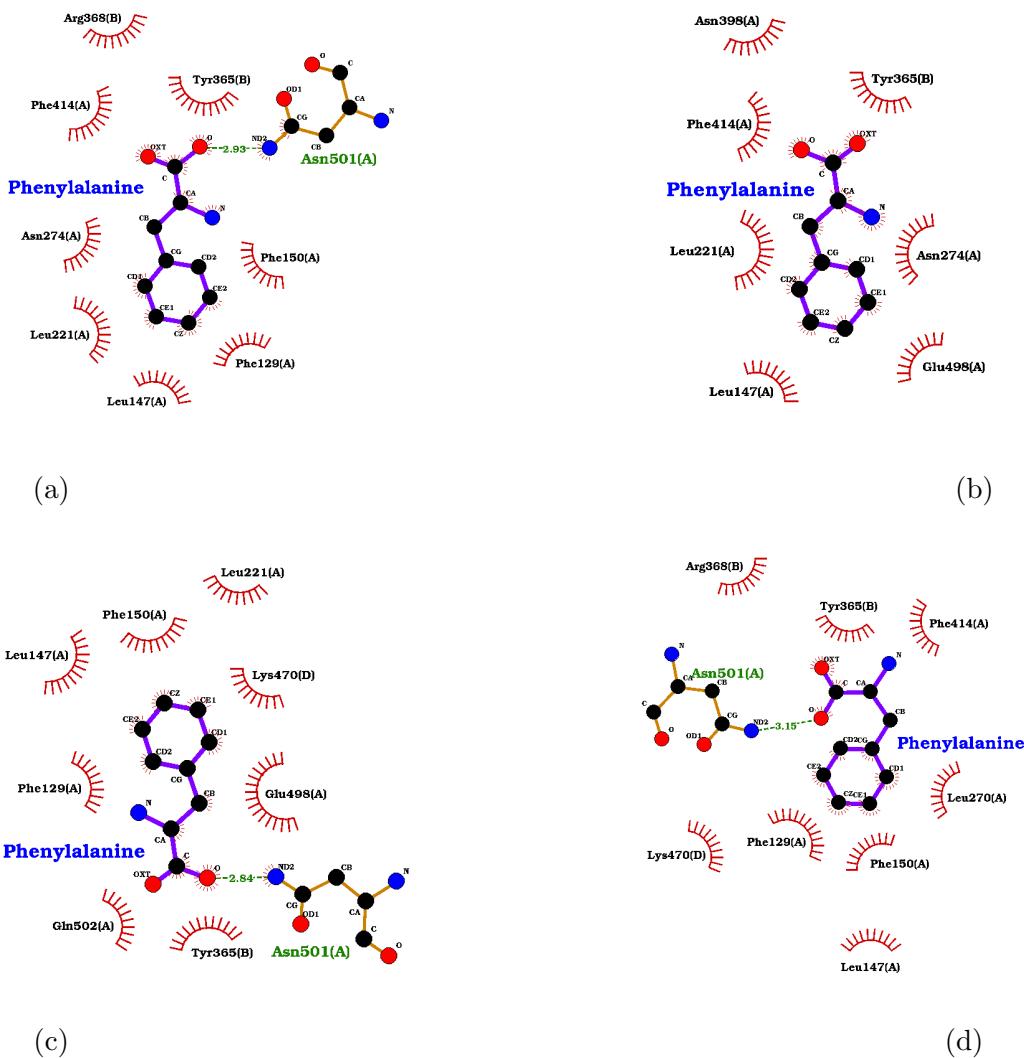

Figure 3: Interactions of phenylalanine with Pn8.2617. Best four poses are shown in order a-d.

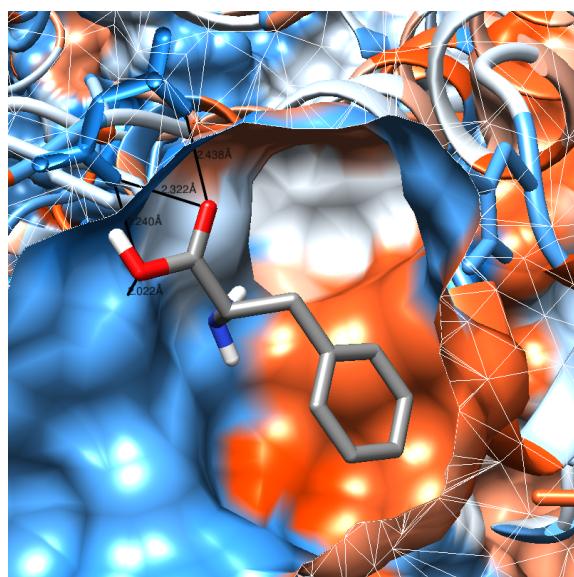

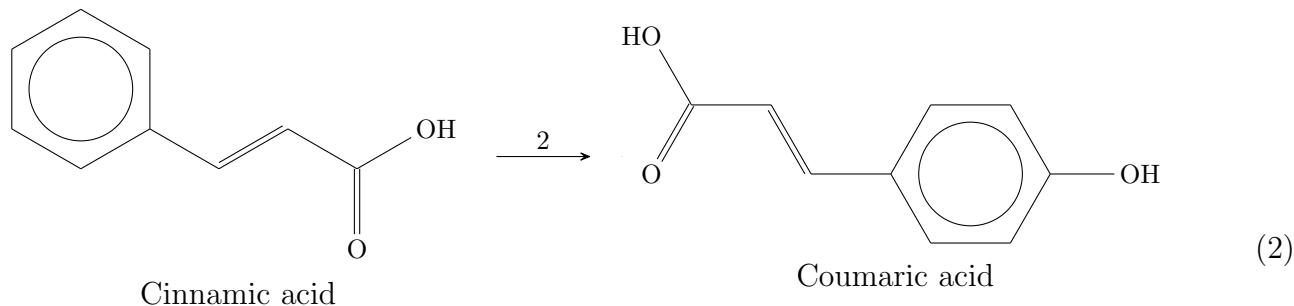

Figure 4: Phenylalanine pseudobonds with Pn8.2617.

## 1.2 Pn2.84

The second reaction of the pathway (Eq. 2) is catalyzed by a protein from the Cytochrome P450 Monooxygenase family called trans-cinnamate 4-hydroxylase, this enzyme is also part of the phenylpropanoid biosynthesis pathway. The gene Pn2.84 was selected as the best candidate for enzyme 2 based on the fact that it obtained the highest score (985.2) over the threshold (555.2) for KEGG Orthology ID K00487, with E-value =  $2.5 \times 10^{-297}$ . This annotation was made with KofamKOALA.<sup>4</sup> With the exon usage analysis no relevant results were found.

The gene contains four exons that were considered when modeling the three-dimensional structure of the protein. The structure modeling was made by using an homology based methodology “SWISS-MODEL”.<sup>33</sup> The selected template was a cinnamate 4-hydroxylase from *Sorghum bicolor* with PDB ID: 6VBY; this protein has a 77.91% sequence identity to our query protein Pn2.84 which makes it an appropriate template. The template was found with HHblits, a protein sequence searching algorithm that uses hmm-hmm alignment.<sup>23</sup> The model (Fig. 5) is found in a monomeric state, as the template is; it has a GMQE value of 0.91 and a QMEANDisCo Global value of  $0.91 \pm 0.05$  (Fig. 6).<sup>26</sup> The enzyme requires an heme molecule as a coenzyme for its correct catalytic activity; in the template a protoporphyrin IX containing Fe was found, which was used as a coenzyme for Pn2.84. The ligand 3D conformer structure was obtained from PubChem with CID: 5957728.

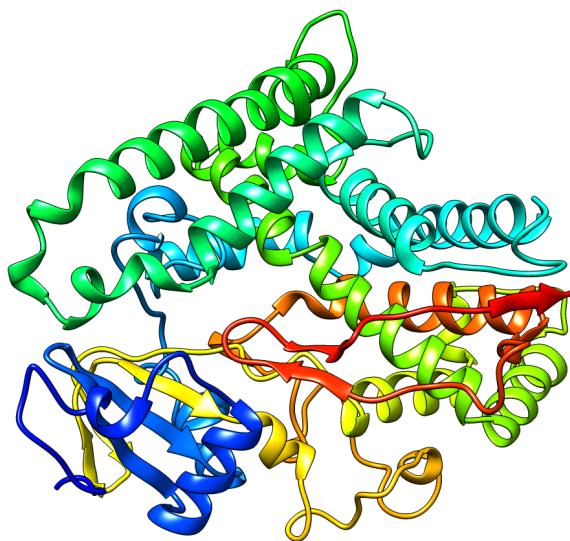

Figure 5: Pn2.84 three-dimensional model.

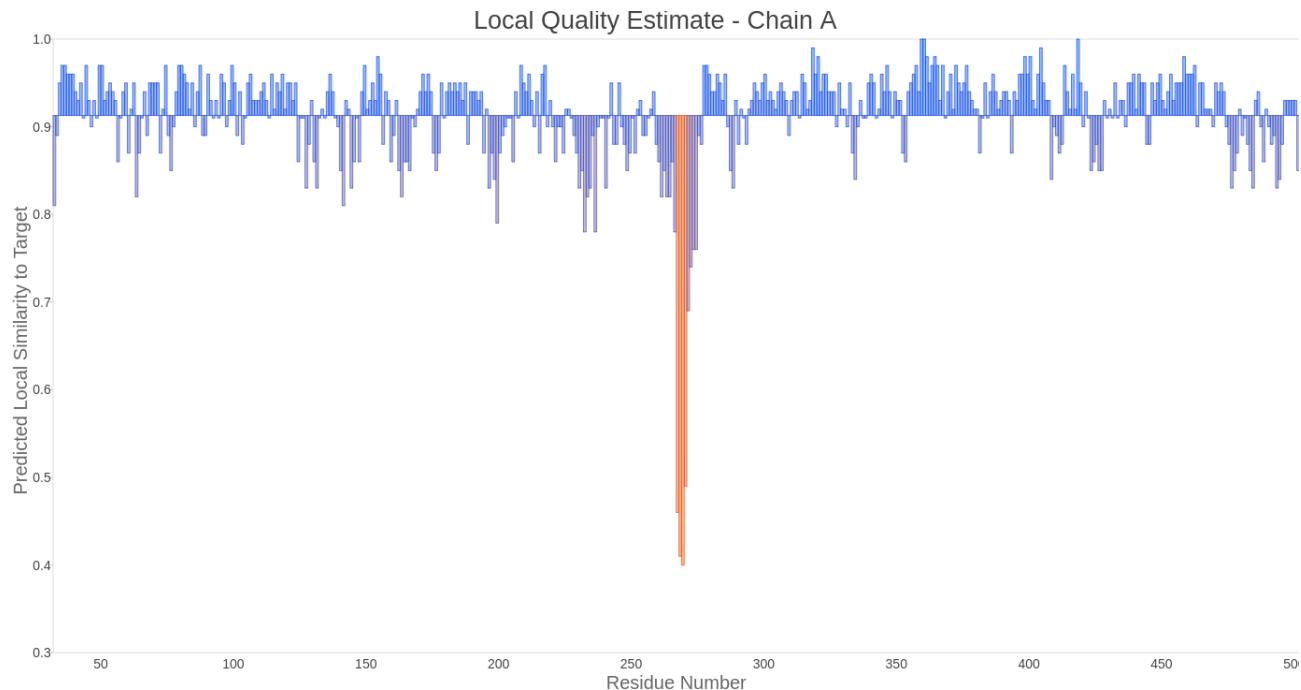

Figure 6: Pn2.84 model QMEANDisCo.

Before docking was performed the protein and the ligand were energy minimized. The protein structure was minimized using UCSF ChimeraX software<sup>21;11</sup> and the steepest descent algorithm for 1000 steps with a step size of 0.02 Å; the force field AMBER ff14SB was used for standard residues, for non standard residues the semi-empirical AM1-BCC model.<sup>13;14;31</sup> In the same way the ligand was energy minimized by using the python library “rdkit” and the MMFF94 force field implemented within it.<sup>15;29</sup>

The preparation of the molecules for docking was made on AutoDockTools and Autodock Vina version 1.2.3 docked the protein and the ligand.<sup>20;8;30</sup> The grid box for the docking was selected based on the conserved domains found with the NCBI conserved domain search interface; we found the heme binding site and putative chemical substrate binding pocket conserved domains for trans-cinnamate 4-hydroxylase from the NCBI-Curated Domains database; additionally, active site residues were selected from the template structure, which included mainly Arg 213, Ser 214 and Gln 218.<sup>16;17</sup> CASTp3 found the protein’s pockets.<sup>28</sup> To perform an adequate docking of both the heme group and the cinnamate molecule a sequential docking workflow was used as described in Vass et al. 2012; in this methodology the protein and ligand were prepared (energy minimized) before the docking was performed, then the first molecule was docked to the protein, the best pose was merged with the protein and this complex was used as a the receptor to dock the next compound.

### 1.2.1 Protoporphyrin IX with Fe

The first molecule docked was the protoporphyrin IX with Fe, as a result of molecular docking with Vina, nine different conformations of the molecule in the protein were found, these results are shown in Table 2. The docked positions of the protoporphyrin IX with Fe in the Pn2.84 structure interacted with different aminoacid residues of the protein (Fig. 7). Some of these aminoacids were found in the conserved domain for the heme binding site of the enzyme, like Arg 101, Trp 126, Arg 130, Phe 138, Met 186, Ile 303, Ala 306, Ala 307, Thr 310, Thr 311, Leu 374, Val 375, His 377, Pro 439, Phe 440, Gly 441, Arg 445, Ser 446, Cys 447, Pro 448, Gly 449, Leu 452, and Ala 453; the rest of the aminoacids were not marked as conserved in the heme binding site domain but were present in the pockets found by CASTp3: Leu 91, Met 117, Val 118, Met 133, Ser 314, Ile 365, Ile 371 and Leu 457.

Table 2: Docking results of protoporphyrin IX (Fe) with Pn2.86

Mode	Affinity (kcal/mol)	Dist. from best mode RMSD l.b	RMSD u.b
1	-9.795	0	0.0
2	-8.72	0.7843	6.157
3	-8.471	2.831	7.051
4	-8.274	3.895	8.459
5	-7.935	2.005	4.936
6	-7.545	2.033	6.57
7	-6.66	3.496	8.093
8	-6.646	3.464	7.518
9	-6.506	2.739	6.189

A further analysis was carried out to elucidate the protein-ligand interactions of the best conformation obtained, which has a binding energy of -9.795 kcal/mol. A search for hydrogen bonds was performed using UCSF ChimeraX allowing relax constraints of 0.4 Å and 20 degrees.<sup>21;11;19</sup> Eight pseudobonds were found between the ligand and four aminoacids of the protein: three pseudobonds with Arg 101 with distances 2.033 Å, 2.169 Å and 2.206 Å; one pesudobond with Trp 126 of 2.197 Å; one with His 377 of 2.104 Å; and three with Arg 445 with distances 1.964 Å, 2.128 Å and 2.238 Å. In Fig. 8 this pseudobonds and the ligand in its pocket are shown, the surface of the protein is colored based on its hydrophobicity using Kyte-Doolittle scale from lower (blue) to higher hydrophobicity (red).

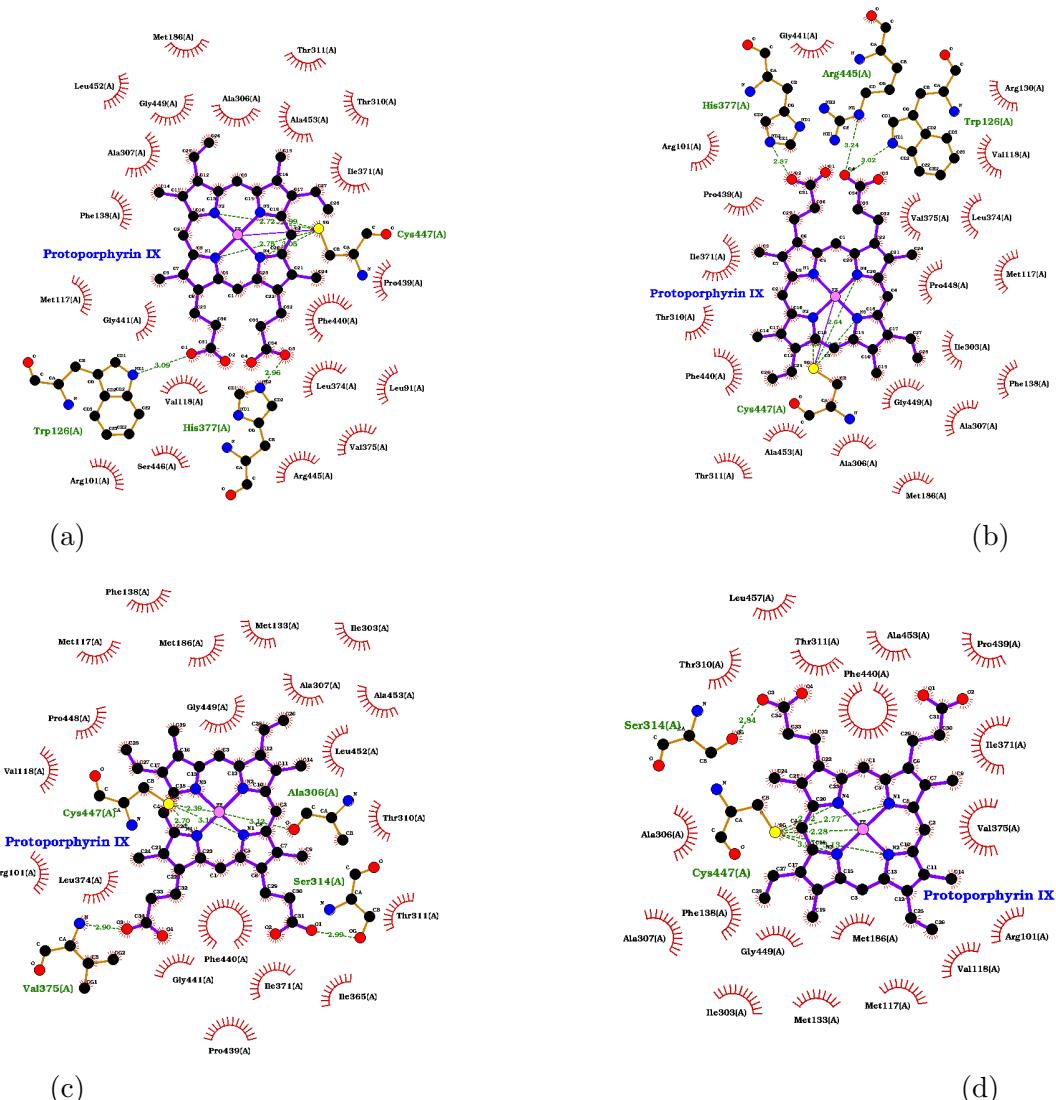

Figure 7: Interactions of protoporphyrin IX with Fe and Pn2.84. Best four poses are shown in order a-d.

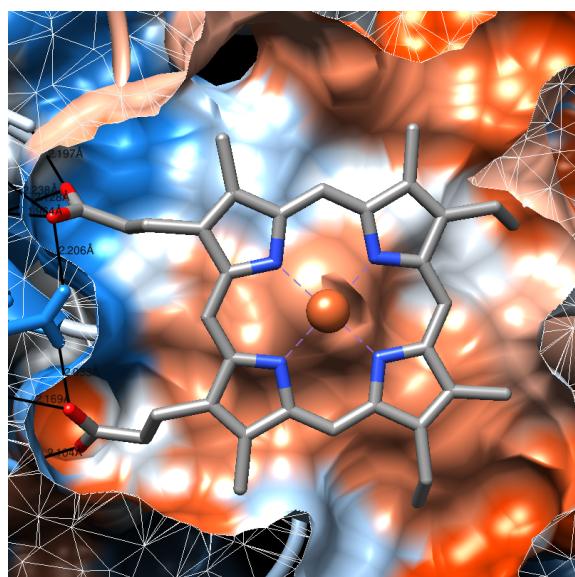

Figure 8: Protoporphyrin IX pseudobonds with Pn2.84.

### 1.2.2 Cinnamic acid

With the Pn2.84 protein and the best docked pose of protoporphyrin IX with Fe as a complex, molecular docking using Vina was carried out for trans-cinnamic acid resulting in nine different conformations, these results are shown in Table 3. The docked positions of the trans-cinnamic acid in the receptor structure interacted with different aminoacid residues of the protein (Fig. 9). Some of these aminoacids were found in the conserved domain for the active site of the enzyme, like Phe 107, Val 118, Phe 119, Arg 213, Ser 214, Gln 218, Val 305, Ala 306, Ile 371 and Val 375; the rest of the aminoacids were not marked as conserved in the active site domain but were present in the pockets found by CASTp3: Thr 310, Trp 313, Leu 374, Pro 376 and Phe 488.

Table 3: Docking results of cinnamic acid with protoporphyrin IX-Pn2.86 complex

Mode	Affinity (kcal/mol)	Dist. from best mode RMSD l.b	RMSD u.b
1	-6.66	0	0
2	-6.359	2.652	3.093
3	-6.147	1.105	1.982
4	-5.586	2.381	2.985
5	-5.577	3.276	5.403
6	-5.57	3.049	3.496
7	-5.414	5.377	5.865
8	-5.291	2.987	3.666
9	-5.271	4.219	5.511

A search for hydrogen bonds was performed with the best conformation (-6.66 kcal/mol) using UCSF ChimeraX allowing relax constraints of 0.4 Å and 20 degrees.<sup>21;11;19</sup> Four pseudobonds were found between the ligand and four aminoacids of the protein: two pseudobonds with Arg 213 with distances 2.378 Å and 2.539 Å; one pesudobond with Ser 214 of 2.329 Å; and one with Gln 218 of 2.312 Å. In Fig. 10 this pseudobonds and the ligand in its pocket are shown, also the distance between the trans-cinnamate and the Fe atom of the heme group is represented; the surface of the protein is colored based on its hydrophobicity using Kyte-Doolittle scale from lower (blue) to higher hydrophobicity (red). Reliability of the docking is supported by the fact that strong interactions between cinnamic acid and aminoacid residues Arg 213, Ser 214 and Gln 218 were found, consistent with what is found in the template crystal structure and the conserved domain for the active site. The interaction found between the cinnamic acid and the heme group and the slightly smaller distance between the cinnamic acid and the Fe atom found in this analysis compared to Zhang et al. 2020 (4.142 Å vs 4.4 Å), provide also a strong support for this docking methodology.

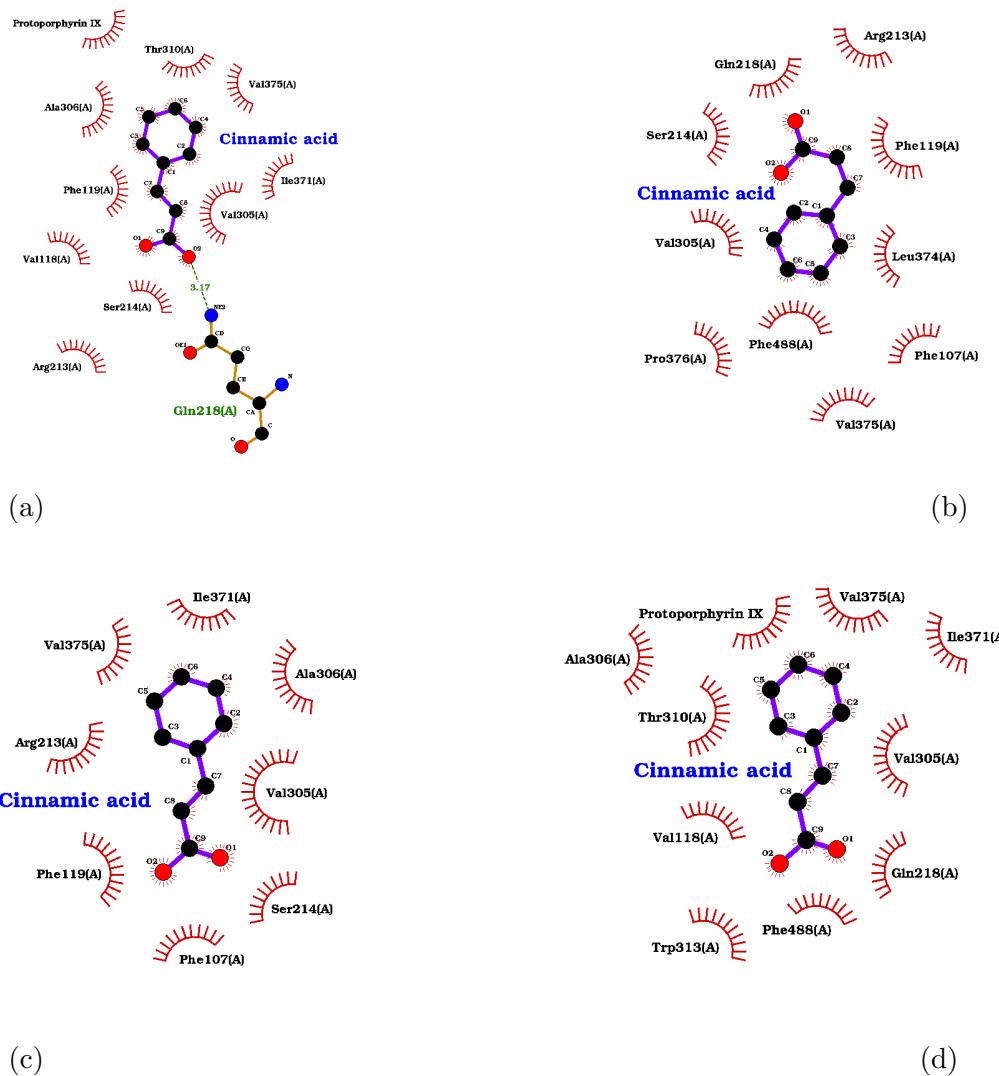

Figure 9: Interactions of cinnamic acid with protoporphyrin IX-Pn2.86 complex. Best four poses are shown in order a-d.

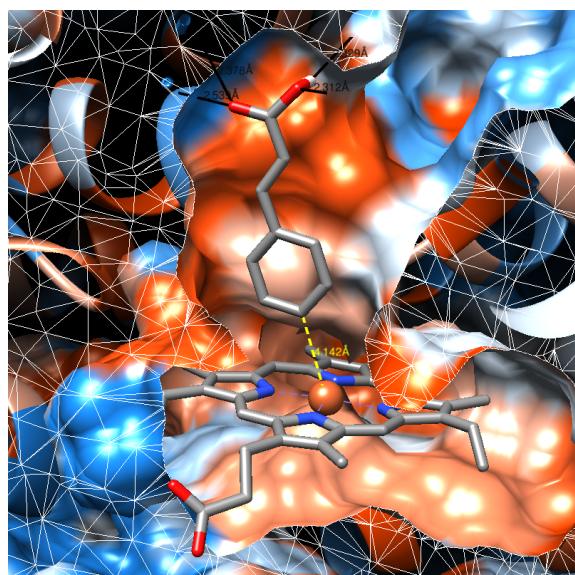

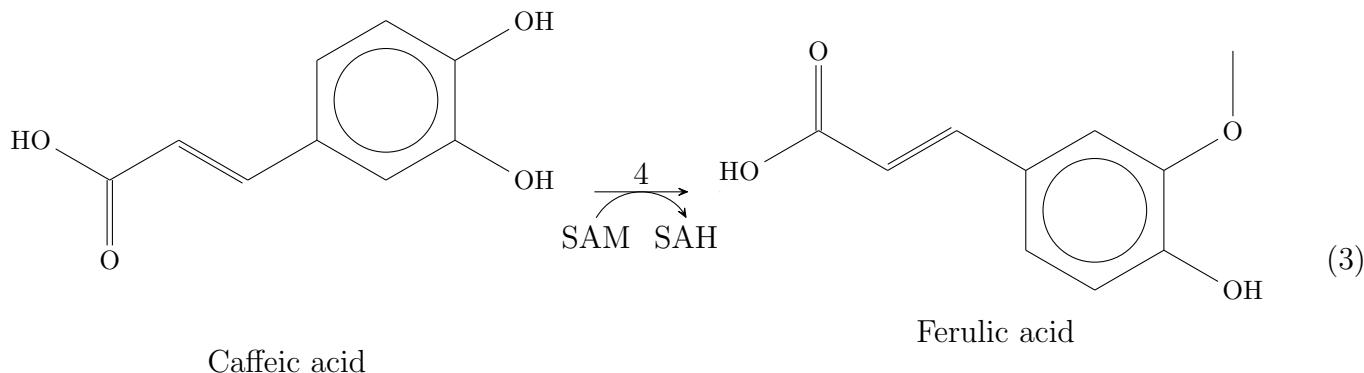

Figure 10: Cinnamic acid pseudobonds with protoporphyrin IX-Pn2.86 complex.

### 1.3 Pn1.1317

The fourth reaction of the pathway (Eq. 3) is catalyzed by the protein caffeic acid 3-O-methyltransferase, this enzyme is also part of the phenylpropanoid biosynthesis pathway. The gene Pn1.1317 was selected as the best candidate for enzyme 4 based on the fact that it obtained the highest score (651.5) over the threshold (499.33) for KEGG Orthology ID K13066, with E-value =  $2.9 \times 10^{-196}$ . This annotation was made with KofamKOALA.<sup>4</sup> With the exon usage analysis no relevant results were found.

The gene contains four exons that were considered when modeling the three-dimensional structure of the protein. The structure modeling was made by using an homology based methodology “SWISS-MODEL”.<sup>33</sup> The selected template was an O-methyltransferase from *Fragaria ananassa* with PDB ID: 6I71; this protein has a 68.39% sequence identity to our query protein Pn1.1317 which makes it an appropriate template. The template was found with HHblits.<sup>23</sup> The model (Fig. 11) is found in a dimeric state, as the template is; it has a GMQE value of 0.84 and a QMEANDisCo Global value of  $0.81 \pm 0.05$  (Fig. 12).<sup>26</sup> The enzyme requires a coenzyme SAM (S-adenosylmethionine) for its correct catalytic activity; this molecule is demethylated to SAH (S-adenosyl-L-homocysteine). The crystal structure of the template contained SAH binded to it, the binding site for SAH was conserved in Pn1.1317 so the model generated contained this molecule, the interactions between this ligand and the protein can be seen in Fig 13. The ligand 3D conformer structure for SAM and caffeic acid were obtained from PubChem with CIDs: 34755 and 689043.

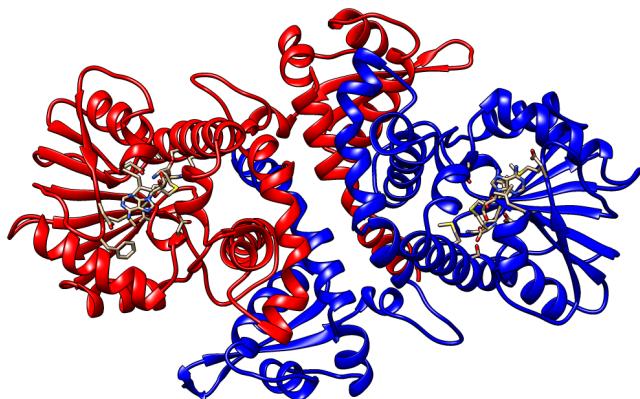

Figure 11: Pn2.84 three-dimensional model.

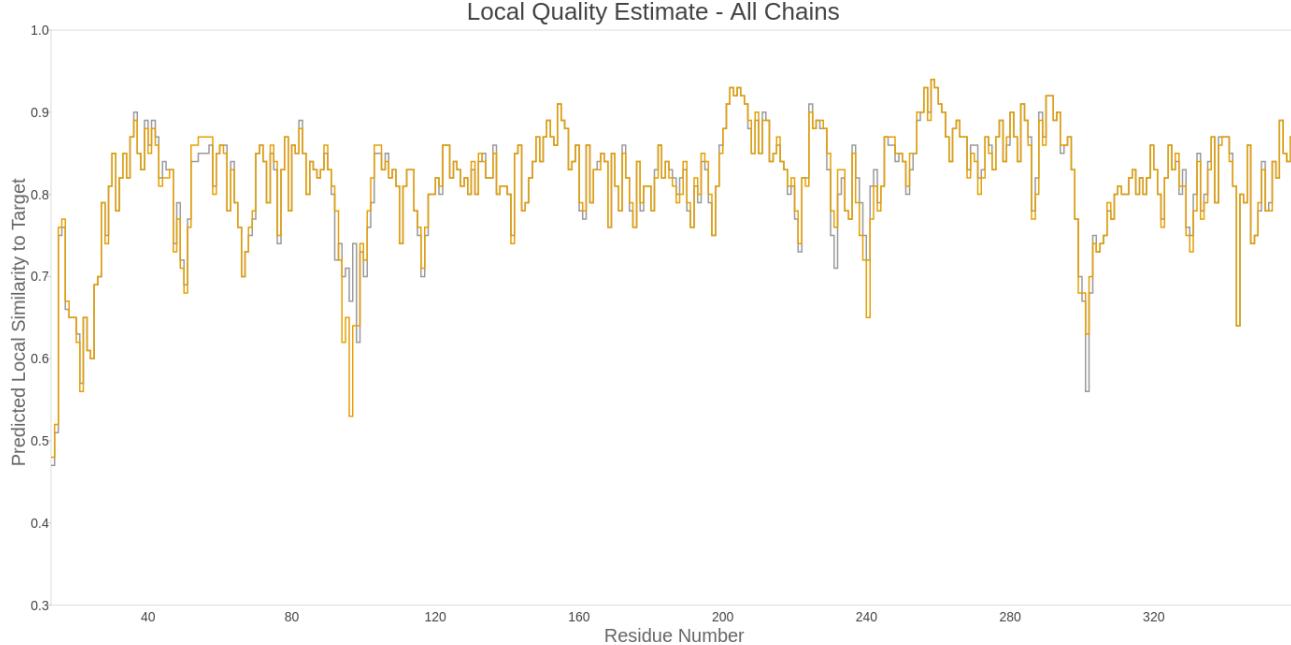

Figure 12: Pn1.1317 model QMEANDisCo.

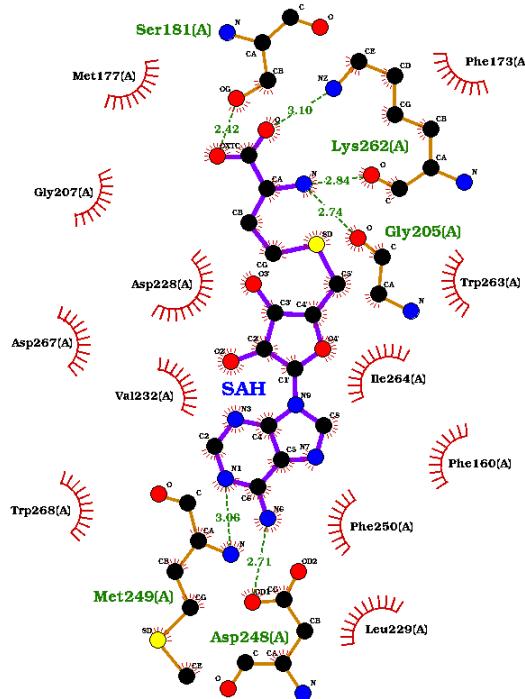

Figure 13: Interactions between SAH and Pn1.1317.

Before docking was performed the protein and the ligand were energy minimized. The protein structure was minimized using UCSF ChimeraX software<sup>21;11</sup> and the steepest descent algorithm for 1000 steps with a step size of 0.02 Å; the force field AMBER ff14SB was used for standard residues, for non standard residues the semi-empirical AM1-BCC model.<sup>13;14;31</sup> In the same way the ligands were energy minimized by using the python library “rdkit” and the MMFF94 force field implemented within it.<sup>15;29</sup>

The preparation of the molecules for docking was made on AutoDockTools and Autodock Vina version 1.2.3 docked the protein and the ligand.<sup>20;8;30</sup> The grid box for the SAM docking was selected based on the conserved binding site for SAH found by homology modeling. In order to know the binding site for caffeic acid, blastp against PDB database was used to obtain similar

protein sequences to Pn1.1317; 11 sequences with identity higher than 50% were selected.<sup>1;2</sup> Muscle aligned the sequences and based on the MSA (Multiple Sequence Alignment) a search for the best aminoacid substitution model was carried out using MEGA 11; the selected model was LG+G (lnL: -4126.121) this decision was supported by Bayesian Information Criterion (BIC: 8436.596) and Akaike's Information Criterion (8296.475).<sup>9;27</sup> With the selected model and the MSA a Maximum Likelihood tree

(ML) was build using MEGA 11, an heuristic search using Nearest Neighbour Interchange was performed and the branch support values were obtained from 100 Bootstrap pseudoreplicates.<sup>27</sup> Using the ML tree topology as a start point, a Bayesian Inference tree (BI) was build using MrBayes; two runs of four chains (1 cold chain and 3 heated chains) were run for one million generations and sampled every one thousand generations with a burn in of 25%, the amino acid substitution model was selected by sampling all of the fixed-rate models implemented in the program, in this way each model will contribute in proportion to its posterior probability.<sup>25</sup>

This analysis was run in the CIPRES Science Gateway portal.<sup>18</sup> To verify if convergence was reached, the results were analyzed with Tracer, the effective sample size for all the parameters was higher than 200: the log likelihood of the cold chain (LnL: 1721; Fig 14), the log likelihood of the prior (LnPr: 1668) and the total tree length (TL: 1658).<sup>22</sup> The resulting tree of the BI analysis can be seen in Fig. 15 Based on this results, the sequence with PDB ID: 1KYW, a Caffeic Acid/5-hydroxyferulic acid 3/5-O-methyltransferase from *Medicago sativa* was selected to define the binding site for caffeic acid. It is part of the sister group of Pn1.1317 and had the most significant alignment E-value ( $2 \times 10^{-180}$ ).

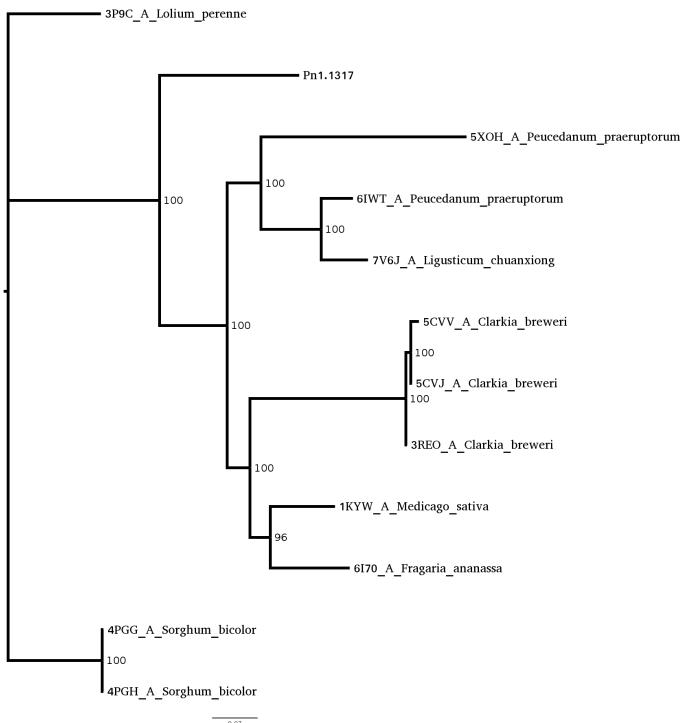

Figure 15: Phylogeny of Pn1.1317, Bayesian Inference.

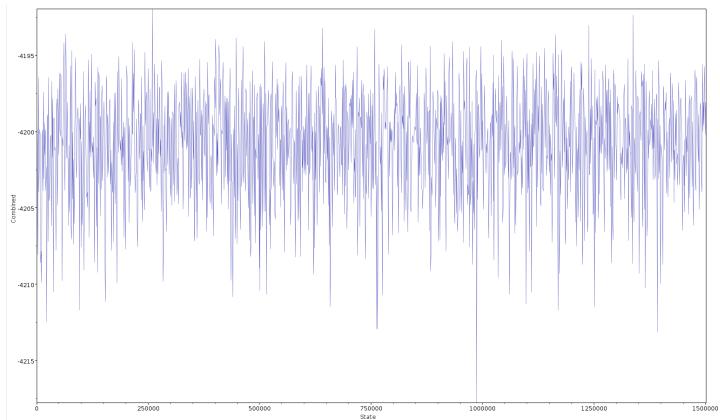

Figure 14: Convergence of log likelihood of the cold chain, BI analysis of Pn1.1317 phylogeny.

Based on the results obtained for this protein by Zubieta et al. 2002, the interactions the substrate HFL (5-(3,3-dihydroxypropenyl)-3-methoxy-benzene-1,2-diol) with 1KYW from the crystallographic structure (Fig. 16) and its homology with Pn1.1317 eleven aminoacid residues were selected as putative binding site for caffeic acid: Met 127, Leu 133, Ala 159, Phe 173, Met 177, Asp 267, Val 313, Ile 316, Met 317, His 320 and Asn 321.

CASTp3 found the protein's pockets.<sup>28</sup> To perform an adequate docking of both the SAM molecule and the caffeic acid, a sequential docking workflow was used as described in Vass et al. 2012 and in section 1.2.

### 1.3.1 SAM

The first molecule docked was the SAM molecule, as a result of molecular docking with Vina, nine different conformations of the molecule in the protein were found, these results are shown in Table 4. The docked positions of the protoporphyrin IX with Fe in the Pn2.84 structure interacted with different aminoacid residues of the protein (Fig. 17). Some of these aminoacids were found in the conserved domain for the SAM/SAH binding site of the enzyme, like Phe 160, Phe 173, Met 177, Ser 181, Gly 205, Gly 207, Asp 228, Leu 229, Val 232, Asp 248, Met 249, Lys 262, Trp 263, Ile 264, Asp 267 and Trp 268; the rest of the aminoacids were not marked as conserved in the heme binding site domain but were present in the pockets found by CASTp3: Asn 174, Ser 178, Gly 206, Ala 211, Phe 227 and Gly 247. In Fig. 18 the SAM in its pocket is shown, the surface of the protein is colored based on its hydrophobicity using Kyte-Doolittle scale from lower (blue) to higher hydrophobicity (red).

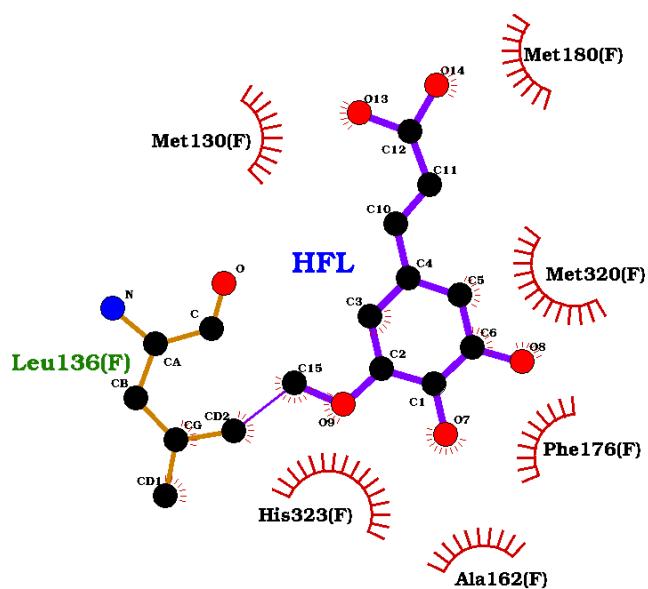

Figure 16: Interactions between caffeoic acid and 1KYW.

Table 4: Docking results of SAM with Pn1.1317

Mode	Affinity (kcal/mol)	Dist. from best mode RMSD l.b	Dist. from best mode RMSD u.b
1	-8.594	0	0
2	-8.476	1.118	1.323

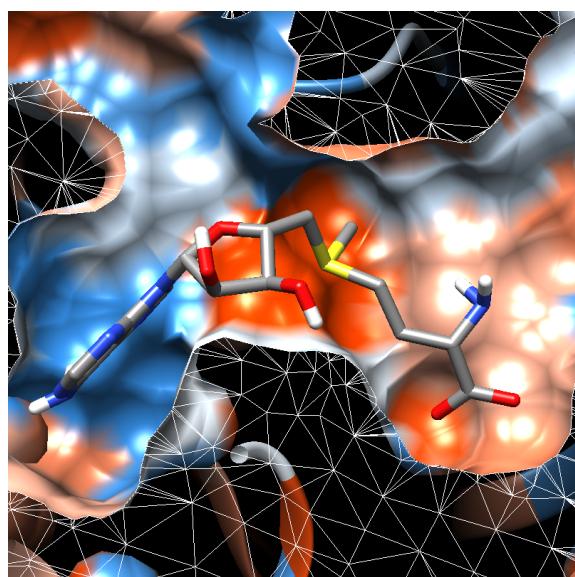

Figure 18: SAM in pocket of Pn1.1317.

## 1.4 Caffeic acid

With the Pn1.1317 protein and the best docked pose of SAM as a complex, molecular docking using Vina was carried out for caffeic acid resulting in nine different conformations, these results are shown in Table 5. The docked positions of the caffeic acid in the receptor structure interacted with different aminoacid residues of the protein (Fig. 19). Some of these aminoacids were found between the residues considered the active site of the enzyme and important for caffeic acid binding according to Zubieta et al. 2002: the hydrophobic residues Met 127, Phe 173, Met 177 and Met 317 sequester the phenyl ring that presents the reactive hydroxyl group to SAM, the residues Asp 267 and Asn 321 form hydrogen bonds with 5-OH group, interactions with the residues Asn-128, Met 127, Met 177, Val 313, and Ile 316 are necessary to bind the propanoid tail; the rest of the aminoacids were not marked as conserved in the active site domain but were present in the pockets found by CASTp3: Met 21, Leu 124, Trp 263 and His 266. In Fig. 20 the best docking pose of caffeic acid with SAM-Pn1.1317 in its pocket is shown, the surface of the protein is colored based on its hydrophobicity using Kyte-Doolittle scale from lower (blue) to higher hydrophobicity (red).

## Contents

<b>Introduction</b>	<b>2</b>
<b>1 Docking</b>	<b>4</b>
1.1 Pn8.2617 . . . . .	4
1.2 Pn2.84 . . . . .	8
1.2.1 Protoporphyrin IX with Fe . . . . .	10
1.2.2 Cinnamic acid . . . . .	12
1.3 Pn1.1317 . . . . .	14
1.3.1 SAM . . . . .	17
1.4 Caffeic acid . . . . .	19

## List of Figures

1 Pn8.2617 three-dimensional model. . . . .	4
2 Pn8.2617 model QMEANDisCo. . . . .	5
3 Interactions between phenylalanine and Pn8.2617 . . . . .	7
4 Phenylalanine pseudobonds with Pn8.2617. . . . .	7
5 Pn2.84 three-dimensional model. . . . .	8
6 Pn2.84 model QMEANDisCo. . . . .	9
7 Interactions between protoporphyrin IX with Fe and Pn2.84 . . . . .	11
8 Protoporphyrin IX pseudobonds with Pn2.84. . . . .	11
9 Interactions between cinnamic acid and protoporphyrin IX-Pn2.86 complex. . . . .	13
10 Cinnamic acid pseudobonds with protoporphyrin IX-Pn2.86 complex. . . . .	13
11 Pn2.84 three-dimensional model. . . . .	14
12 Pn1.1317 model QMEANDisCo. . . . .	15
13 Interactions between SAH and Pn1.1317. . . . .	15
14 Convergence of lnL, BI analysis of Pn1.1317. . . . .	16
15 Phylogeny of Pn1.1317, Bayesian Inference. . . . .	16
16 Interactions between caffeic acid and 1KYW. . . . .	17
17 Interactions between SAM and Pn1.1317. . . . .	18
18 SAM in pocket of Pn1.1317. . . . .	18
19 Interactions between caffeic acid and SAM-Pn1.1317 complex. . . . .	20
20 Caffeic acid in pocket of SAM-Pn1.1317 complex. . . . .	20

## List of Tables

1 Docking results of phenylalanine in Pn8.2617 . . . . .	6
2 Docking results of protoporphyrin IX (Fe) with Pn2.86 . . . . .	10

---

3	Docking results of cinnamic acid with protoporphyrin IX-Pn2.86 complex . . . . .	12
4	Docking results of SAM with Pn1.1317 . . . . .	17
5	Docking results of caffeic acid with SAM-Pn1.1317 complex . . . . .	19
